# 6.1 An Introduction to Vectors

## Definition 6.1.1

A **vector** is a **mathematical object** which carries **two characteristics**:

- 1) Magnitude (size or length)
- 2) Direction

Geometrically we can think of (or visualize) vectors as **directed line segments**

Picture

Notes:

$$\vec{AB} = \vec{CD}$$

$$\vec{AB} \neq \vec{EF}$$

(different directions)

## Some Basic Notations

1) In general we “write” vectors (or algebraically represent vectors):

a) With **capital letters** indicating the “**tip**” and “**tail**” points of the vector

b) With a single lower case letter

2) We write the **Magnitude** of vectors with “absolute value bars”

(**KNOW YOUR CONTEXT!**)

e.g. The magnitude of  $\vec{a}$  is given by

$$|\vec{a}|$$

The magnitude of  $\vec{AB}$  is

$$|\vec{AB}|$$

Concerning Magnitude

a) **Magnitude** is just a **number**

b) The **magnitude** of any vector is always **positive** (since it represents the **length** of the vector).

non-negative

$$|\vec{a}| \geq 0$$

3) Two vectors  $\vec{a}$  and  $\vec{b}$  are said to be **equal** (or **equivalent**) if:

a)  $|\vec{a}| = |\vec{b}|$

b) The same direction.

Pictures

$$\vec{a} = \vec{b}$$

$$\vec{a} \neq \vec{b} \text{ even though } |\vec{a}| = |\vec{b}|$$

numbers without direction.

4) A **scalar** is a (mathematical) quantity which can "scale" vectors (describing size)

Examples:

Magnitude is a scalar (length is a number!)

Speed is a scalar (eg 45 km/hr)

Velocity is a vector (eg 45 km/hr [E])  
 magnitude direction.

Scalars can "stretch" or "shrink" vectors (in terms of magnitude).

Scalars can be negative.

Picture:

$$2\vec{a} = \vec{b}$$

or

$$\vec{a} = \frac{1}{2}\vec{b}$$

negative scalars reverse direction

$$-2\vec{c} = \vec{a}$$

or

$$-4\vec{c} = \vec{b}$$

**Comment**

$$\text{Let } |\vec{c}| = 3|\vec{a}|$$

$$\text{Then } \vec{c} = 3\vec{a}$$

CANNOT BE CONCLUDED because we don't have info about direction

Q. Can we write

$$\vec{c} = 3|\vec{a}|$$

vector scalar

No : vectors cannot equal scalars!

5) If  $\vec{a} = -\vec{b}$ , then we have that

a)  $\vec{a}$  and  $\vec{b}$  are pointing in opposite directions, but

b)  $|\vec{a}| = |\vec{b}|$

We sometimes call  $\vec{a}$  and  $\vec{b}$  *opposite vectors*

### Example 6.1.1

Given the vector

Draw a)  $\vec{b}$  so that  $|\vec{b}| = |\vec{a}|$  but  $\vec{b} \neq \vec{a}$

b)  $\vec{c}$  so that  $\vec{c} = 2\vec{a}$

b)

(same direction as  $\vec{a}$ )

### Example 6.1.2

Using a scale of  $1\text{ cm} = 5\text{ km/hr}$  draw a vector which represents  $25\text{ km/hr}$   $[S 60^\circ E]$

*obviously this is 5 cm long*
